

CLOCK DISTRIBUTION CIRCUIT

IDT6T39007A

Description

The IDT6T39007A is a low-power, four output clock distribution circuit. The device takes a TCXO or 1.8 V to 2.5 V LVCMOS input and generates four high-quality LVDS outputs, and two programmable divided outputs.

It includes a redundant input with automatic glitch-free switching when the primary reference is removed. The primary input may be selected by the user by pulling the SEL pin low or high. If the primary input is removed and brought back, it will not be re-selected until 1024 cycles have passed.

The IDT6T39007A specifically addresses the needs of handheld applications in both performance and package size. The device is packaged in a small 4mm x 4mm 24-pin QFN, allowing optimal use for limited board space.

Features

- Packaged in 24-pin QFN
- TCXO sine wave input
- +2.5 V operating voltage
- Four buffered LVDS outputs
- Two programmable outputs for power control up to 3.0 V LVCMOS levels based on VDDO1/VDDO2
- Individual output enables controlled via I²C or OEx
- Pb-free, RoHS compliant package
- Industrial temperature range (-40°C to +85°C)

General I²C Serial Interface

How to Write:

- Controller (host) sends a start bit
- Controller (host) sends the write address D4_(H)
- IDT clock will *acknowledge*
- Controller (host) sends the beginning byte location =N
- IDT clock will *acknowledge*
- Controller (host) sends the data byte count = X
- IDT clock will *acknowledge*
- Controller (host) starts sending *Byte N through Byte N + X - 1* (see Note 2)
- IDT clock will *acknowledge* each byte *one at a time*
- Controller (host) sends a Stop bit

I²C Address

The IDT6T39007A is a slave-only device that supports block read and block write protocol using a single 7 bit address and read/write bit. A block write (D4_(H)) or block read (D5_(H)) is made up of seven (7) bits and one (1) read/write bit.

A6	A5	A4	A3	A2	A1	A0	R/W#
1	1	0	1	0	1	0	X

In applications where the indexed block write and block read are used, the dummy byte (bit 11-18) functions as a register-offset (8 bits) pointer.

Applications Information

External Components

A minimum number of external components are required for proper operation.

Decoupling Capacitors

Decoupling capacitors of 0.01 μF should be connected between VDD and GND as close to the device as possible. Do not share ground vias between components. Route power from power source through the capacitor pad and then into IDT pin.

PCB Layout Recommendations

For optimum device performance and lowest output phase noise, the following guidelines should be observed.

1. Each 0.01 μF decoupling capacitor should be mounted on the component side of the board as close to the VDD pin as possible.
2. No vias should be used between decoupling capacitor and VDD pin.
3. The PCB trace to VDD pin should be kept as short as possible, as should the PCB trace to the ground via. Distance of the ferrite bead and bulk decoupling from the device is less critical.
4. An optimum layout is one with all components on the same side of the board, minimizing vias through other signal layers (any ferrite beads and bulk decoupling capacitors can be mounted on the back). Other signal traces should be routed away from the IDT6T39007A. This includes signal traces just underneath the device, or on layers adjacent to the ground plane layer used by the device.

Absolute Maximum Ratings

Stresses above the ratings listed below can cause permanent damage to the IDT6T39007A. These ratings, which are standard values for IDT commercially rated parts, are stress ratings only. Functional operation of the device at these or any other conditions above those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions for extended periods can affect product reliability. Electrical parameters are guaranteed only over the recommended operating temperature range.
